

# Induced and coinduced modules in cluster-tilted algebras

Khrystyna Nechyporenko<sup>\*</sup>

---

Let  $C$  be a tilted algebra and  $B$  the corresponding cluster-tilted algebra. We consider induction from  $\text{mod } C$  to  $\text{mod } B$  via the tensor product with  $B$ . It turns out that this functor has some interesting properties such as each projective  $B$ -module is induced by the corresponding projective  $C$ -module, but induction of any injective  $C$ -module results in the exact same module. Similarly, we introduce a dual construction called coinduction functor. Using both functors we construct an explicit injective resolution of each projective  $B$ -module. This gives rise to another proof of the known result that cluster-tilted algebras are 1-Gorenstein.

Moreover, if  $B$  is representation finite then every module is both induced and coinduced from some tilted algebra  $C$ . If  $B$  is not representation finite then every transjective module in  $B$  is either induced or coinduced from some  $C$ . However, the situation with regular modules turns out to be more complicated.
