Abstract

Given an undirected hypergraph and a subset of vertices $S$ with a specified root vertex $r$ in $S$, the Steiner Rooted-Orientation problem is to find an orientation of all the hyperedges so that in the resulting directed hypergraph the “connectivity” from the root $r$ to the vertices in $S$ is maximized.

This is motivated by a multicasting problem in undirected networks as well as a generalization of some fundamental problems in graph theory. Our main results are the following approximate min-max relations:

- Given an undirected hypergraph $H$, if $S$ is $2k$-hyperedge-connected in $H$, then $H$ has a Steiner rooted $k$-hyperarc-connected orientation.
- Given an undirected graph $G$, if $S$ is $2k$-element-connected in $G$, then $G$ has a Steiner rooted $k$-element-connected orientation.

Both are optimal in terms of the connectivity bounds. These also imply the first polynomial time constant factor approximation algorithms for both problems. The proof is based on a new use of the submodular flow technique, and a decomposition technique used in the Steiner Tree Packing problem.
