Abstract

Given an undirected hypergraph and a subset of vertices S with a specified root vertex r in S , the Steiner Rooted-Orientation problem is to find an orientation of all the hyperedges so that in the resulting directed hypergraph the “connectivity” from the root r to the vertices in S is maximized.

This is motivated by a multicasting problem in undirected networks as well as a generalization of some fundamental problems in graph theory. Our main results are the following approximate min-max relations:

- Given an undirected hypergraph H , if S is $2k$ -hyperedge-connected in H , then H has a Steiner rooted k -hyperarc-connected orientation.
- Given an undirected graph G , if S is $2k$ -element-connected in G , then G has a Steiner rooted k -element-connected orientation.

Both are optimal in terms of the connectivity bounds. These also imply the first polynomial time constant factor approximation algorithms for both problems. The proof is based on a new use of the submodular flow technique, and a decomposition technique used in the Steiner Tree Packing problem.
