Abstract

A 3-stage 6-step variable step Hermite–Birkhoff–Obrechkoff method of order 14, denoted by HBO14(3,6), is constructed for solving non-stiff systems of first-order differential equations of the form \( y' = f(x, y) \), \( y(x_0) = y_0 \). Its formula uses \( y' \) and \( y'' \) as in Obrechkoff method. Forcing a Taylor expansion of the numerical solution to agree with an expansion of the true solution leads to multistep and Runge–Kutta type order conditions which are reorganized into linear Vandermonde-type systems. Fast algorithms are developed for solving these systems to obtain Hermite–Birkhoff interpolation polynomials in terms of generalized Lagrange basis functions. The new method has a larger region of absolute stability than Adams–Bashforth–Moulton methods of orders 10 to 13 in PECE mode. The stepsize is controlled by a local error estimator. HBO14(3,6) is superior to MATLAB’s \texttt{ode113} in solving several problems often used to test higher order ode solvers based on the number of steps, cpu time, and maximum global error.

Mathematical Subject Classification: Primary 65L06; Secondary 65D05, 65D30

Keywords and phrases: general linear method for nonstiff ode’s, Hermite–Birkhoff method, Obrechkoff method, Vandermonde-type systems, maximum global error, number of function evaluations, cpu time, MATLAB’s \texttt{ode113}, comparing ode solvers

Résumé

On construit un solveur à 3 étages et à 6 pas d’ordre 14 de type Hermite–Birkhoff–Obrechkoff, noté HBO14(3,6), pour systèmes d’équations différentielles non raides \( y' = f(x, y) \), \( y(x_0) = y_0 \), faisant usage de \( y' \) et \( y'' \). On dérive les conditions d’ordre de types Runge–Kutta et multipas en identifiant les coefficients du développement de Taylor de la solution numérique et de la solution exacte qu’on réorganise en systèmes de type Vandermonde. La solution de ces systèmes au moyen de nouveaux algorithmes rapides donne lieu à des polynômes d’interpolation d’Hermite–Birkhoff sur une base de fonctions de Lagrange généralisées. La nouvelle méthode admet un domaine de stabilité absolu plus grand que ceux des méthodes d’Adams–Bashforth–Moulton d’ordre 10 à 13 en mode PECE. Un estimateur de l’erreur locale contrôle le pas. HBO14(3,6) est supérieure à \texttt{ode113} de MATLAB sur des problèmes souvent utilisés pour tester les méthodes d’ordre élevé quant au nombre de pas, au temps machine et à l’erreur globale maximum.
1 Introduction

An explicit 6-step Obrechkoff method [21] and a 3-stage Runge–Kutta method of order 3 are cast into a 3-stage 6-step Hermite–Birkhoff–Obrechkoff method of order 14 named HBO14(3,6) (HBO14, for short, in this paper). The 6 steps consist in the current step and 5 backsteps. The method’s name was chosen because it uses Hermite–Birkhoff interpolation polynomials and first and second order derivatives of $y$ at step points like Obrechkoff methods. The link between the two types of methods is that values at off-step points are obtained by means of predictors which use values at previous points.

Milne [18] was perhaps the first to have advocated the use of multiderivative, multistep Obrechkoff formulae for the numerical solution of differential equations. More recently, Huang and Innanen [14] introduced a new form of the classical Adams–Cowell methods and multiderivative, multistep methods some of which having larger stability interval and smaller truncation error than classical multistep methods.

Scientific computation widely uses variable step, variable order Adams–Bashforth–Moulton multistep methods of orders 1 to 14 as implemented by Gear [9] and [10], Krogh [16], and up to order 13, by Shampine [22] in MATLAB’s ode113 ([2], [23]). The codes DVDQ of Krogh [15] and DIFSUB of Gear [10] prompted the recognition of the effectiveness of a variable order, variable step formulation of Adams methods. When the equation is expensive to evaluate, high-order solvers appear to be more efficient than lower order ones.

HBO14 is designed for solving nonstiff systems of first-order initial value problems of the form

$$y' = f(x, y), \quad y(x_0) = y_0, \quad \text{where} \quad \frac{dy}{dx} = r.$$  \hspace{1cm} (1)

Forcing a Taylor expansion of the numerical solution to agree with an expansion of the true solution leads to multistep and Runge–Kutta type order conditions which are reorganized into linear Vandermonde-type systems. The performance of HBO14 and MATLAB’s ode113 was compared on several problems often used to test higher order ode solvers. It is seen that HBO14 requires fewer steps and lower cpu time, and has higher accuracy than ode113.

Section 2 introduces general variable step HBO14 of order 14. Order conditions are listed in Section 3. In Section 4 this general HBO14 is represented in terms of Vandermonde-type systems. In Section 5 new symbolic algorithms are derived to diagonalize the coefficient matrices of these systems as functions of the parameters of the systems. Section 6 defines a particular variable step HBO14. In sections 7, a particular HBO14 is constructed by a fast solution of the systems. Section 8 considers the region of absolute stability of a constant step HBO14 and its principal local truncation coefficients. Section 9 deals with the step control. In section 10, three criteria are used to compare the performance of the methods considered in this paper. Appendix A lists the algorithms and Appendix B describes the MATLAB programming.

2 General variable step HBO14

A Hermite–Birkhoff–Obrechkoff method is said to be a general variable step Hermite–Birkhoff–Obrechkoff method if its backstep and off-step points are variable parameters. If the off-step points are fixed, the method is said to be a particular variable step method.

A general HBO14 requires the following four formulae to perform the integration step from $x_n$ to $x_{n+1}$. For notational simplicity, $c_1 = 0$ is used in the summations.

(P2) A Hermite–Birkhoff polynomial of degree 12 is used as predictor $P_2$ to obtain $y_{n+c_2}$ to order 12,

$$y_{n+c_2} = y_n + h_{n+1} \left[ a_{21} f_{n+c_1} + \sum_{j=1}^{5} \beta_{2j} f_{n-j} \right] + h_{n+1}^2 \left[ \sum_{j=0}^{5} \gamma_{2j} f_{n-j} \right].$$ \hspace{1cm} (2)

(P3) A Hermite–Birkhoff polynomial of degree 13 is used as predictor $P_3$ to obtain $y_{n+c_3}$ to order 12,

$$y_{n+c_3} = y_n + h_{n+1} \left[ \sum_{j=1}^{2} a_{3j} f_{n+c_j} + \sum_{j=1}^{5} \beta_{3j} f_{n-j} \right] + h_{n+1}^2 \left[ \sum_{j=0}^{5} \gamma_{3j} f_{n-j} \right].$$ \hspace{1cm} (3)

(IF) A Hermite–Birkhoff polynomial of degree 14 is used as integration formula IF to obtain $y_{n+1}$ to order 14,

$$y_{n+1} = y_n + h_{n+1} \left[ \sum_{j=1}^{2} b_{1j} f_{n+c_j} + b_{13} f_{n+c_3} + \sum_{j=1}^{5} \beta_{1j} f_{n-j} \right] + h_{n+1}^2 \left[ \sum_{j=0}^{5} \gamma_{1j} f_{n-j} \right].$$ \hspace{1cm} (4)
A Hermite–Birkhoff polynomial of degree 12 is used as step control predictor $P_4$ to obtain $\tilde{y}_{n+1}$ to order 12,

$$
\tilde{y}_{n+1} = y_n + h_{n+1} \left( a_{41}f_n + a_{43}f_{n+1} + \sum_{j=1}^{4} \beta_{4j} f_{n-j} \right) + h_{n+1}^2 \left( \sum_{j=0}^{5} \gamma_{4j} f'_{n-j} \right). \tag{5}
$$

We note that $f'_{n+1}$ is computed only once at $x_{n+1}$.

The off-step points of HBO14 satisfy the following Runge–Kutta type simplifying conditions:

$$
c_i = \sum_{j=1}^{i-1} a_{ij} + \sum_{\ell=1}^{5} \beta_{\ell i}, \quad i = 2, 3. \tag{6}
$$

## 3 Order conditions for general HBO14

As in similar search for ODE solvers, we impose the following simplifying assumptions [6], [19] on HBO14:

$$
\sum_{j=1}^{i-1} a_{ij} c_j^k + k! B_i(k+1) = \frac{1}{k+1} c_{i+1}^k, \quad \begin{cases} i = 2, 3, \\
                  k = 0, 1, 2, \ldots, 12,
\end{cases} \tag{7}
$$

where

$$
B_i(j) = \sum_{\ell=1}^{5} \beta_{\ell i} \frac{\eta_{\ell+1}^{j-1}}{(j-1)!} + \sum_{\ell=1}^{5} \gamma_{\ell i} \frac{\eta_{\ell+1}^{j-2}}{(j-2)!}, \quad \begin{cases} i = 2, 3, \\
                  j = 0, 1, 2, \ldots, 14,
\end{cases} \tag{8}
$$

and

$$
\eta_j = -\frac{1}{h_{n+1}} (x_n - x_{n+j-1}) = -\frac{1}{h_{n+1}} \sum_{i=0}^{j-1} h_{n-i}, \quad j = 2, 3, \ldots, 6. \tag{9}
$$

Equation (9) will be frequently used in this paper without further reference.

There remain two sets of equations to be solved:

$$
\sum_{i=1}^{3} b_{1i} c_i^k + k! B_1(k+1) = \frac{1}{k+1}, \quad \begin{cases} k = 0, 1, \ldots, 13,
\end{cases} \tag{10}
$$

$$
\sum_{i=2}^{3} b_{1i} \left( \sum_{j=1}^{i-1} a_{ij} c_j^{12} + B_i(13) \right) + B_1(14) = \frac{1}{14!}, \tag{11}
$$

where

$$
B_1(j) = \sum_{\ell=1}^{5} \beta_{1\ell} \frac{\eta_{\ell+1}^{j-1}}{(j-1)!} + \sum_{\ell=1}^{5} \gamma_{1\ell} \frac{\eta_{\ell+1}^{j-2}}{(j-2)!}, \quad \begin{cases} j = 1, \ldots, 15.
\end{cases} \tag{12}
$$

We note that equations (10), for $k = 0, 1, \ldots, 12$, are multistep type order conditions. On the other hand, equation (10) for $k = 13$ and equation (11) are Runge–Kutta type order conditions. The numbers $B_1(k)$, $B_2(k)$ and $B_3(k)$ are associated with $IF$, $P_2$ and $P_3$, respectively.

## 4 Vandermonde-type formulation of general HBO14

### 4.1 The integration formula IF

The 14-vector of the reordered coefficients of integration formula $IF$ (4),

$$
\mathbf{u}^1 = [b_{11}, \gamma_{10}, \beta_{11}, \gamma_{11}, \beta_{12}, \gamma_{12}, \beta_{13}, \gamma_{13}, \beta_{14}, \gamma_{14}, \beta_{15}, \gamma_{15}, b_{13}, b_{12}]^T,
$$

is the solution of the Vandermonde-type system of order conditions

$$
M^1 \mathbf{u}^1 = \mathbf{r}^1. \tag{13}
$$

where

$$
M^1 = \ldots
$$
The solution of the system of order conditions

\[
\begin{bmatrix}
1 & 0 & 1 & 0 & \cdots & 1 & 0 & 1 & 1 \\
0 & 1 & \eta_2 & 1 & \cdots & \eta_6 & 1 & c_3 & c_2 \\
0 & 0 & \eta_2^2/2! & 1 & \cdots & \eta_6^2/2! & \eta_6 & c_3^2/2! & c_2^2/2! \\
\vdots & & & & & & & & \\
0 & 0 & \eta_6^{13}/13! & \eta_6^{12}/12! & \cdots & \eta_6^{13}/13! & \eta_6^{12}/12! & c_3^{13}/13! & c_2^{13}/13!
\end{bmatrix}
\]

(14)

and \( r^1 = r_1(1 : 14) \) has components

\[ r_1(i) = 1/i!, \quad i = 1, 2, \ldots, 14. \]

The leading error term of IF is

\[
\left[ \sum_{j=1}^{5} \beta_{ij} \eta_j^{14+1} + \sum_{j=1}^{5} \gamma_{ij} \eta_j^{13+1} + b_1 \eta_j^{14} + b_12 \eta_j^{14} - \frac{1}{15!} \right] h_{n+1}^{15} y_n^{15}.
\]

4.2 The predictor \( P_2 \)

The 12-vector of the reordered coefficients of predictor \( P_2 \) (2),

\[ u^2 = [a_{21}, \gamma_{20}, \beta_{21}, \gamma_{21}, \beta_{22}, \gamma_{22}, \beta_{23}, \gamma_{23}, \beta_{24}, \gamma_{24}, \beta_{25}, \gamma_{25}]^T, \]

is the solution of the system of order conditions

\[ M^2 u^2 = r^2, \]

where

\[
M^2 = \begin{bmatrix}
1 & 0 & 1 & 0 & \cdots & 1 & 0 \\
0 & 1 & \eta_2 & 1 & \cdots & \eta_6 & 1 \\
0 & 0 & \eta_2^2/2! & 1 & \cdots & \eta_6^2/2! & \eta_6 \\
\vdots & & & & & & \vdots \\
0 & 0 & \eta_6^{13}/13! & \eta_6^{12}/12! & \cdots & \eta_6^{13}/13! & \eta_6^{12}/12!
\end{bmatrix}
\]

(16)

and \( r^2 = r_2(1 : 12) \) has components

\[ r_2(i) = c_i^2/i!, \quad i = 1, 2, \ldots, 12. \]

A truncated Taylor expansion of the right-hand side of (2) about \( x_n \) gives

\[
\sum_{j=0}^{15} S_2(j) h_{n+1}^j y_n^{(j)}
\]

with coefficients

\[ S_2(j) = M^2(j, 1 : 12) u^2 = r_2(j) = \frac{c_j^2}{j!}, \quad j = 1, 2, \ldots, 12, \]

\[ S_2(j) = \sum_{i=1}^{5} \beta_{2i} \eta_{i+1}^{j-1} + \sum_{i=0}^{5} \gamma_{2i} \eta_{i+2}^{j-2}/(j-2)! + \sum_{i=0}^{5} \eta_{i+2}^{j-2}/(j-2)!, \quad j = 13, 14, 15. \]

We note that \( P_2 \) is of order 12 since it satisfies the order conditions

\[ S_2(j) = c_j^2/j!, \quad j = 1, \ldots, 12, \]

and its leading error term is

\[
\left[ S_2(13) - \frac{c_2^{13}}{13!} \right] h_{n+1}^{13} y_n^{(13)}.
\]

4.3 The predictor \( P_3 \)

The 13-vector of the reordered coefficients of predictor \( P_3 \) (3),

\[ u^3 = [a_{31}, \gamma_{30}, \beta_{31}, \gamma_{31}, \beta_{32}, \gamma_{32}, \beta_{33}, \gamma_{33}, \beta_{34}, \gamma_{34}, \beta_{35}, \gamma_{35}, \beta_{35}, a_{32}]^T, \]

is the solution of the system of order conditions

\[ M^3 u^3 = r^3, \]  

(17)
is the solution of the system of order conditions

\[ 4.4 \text{ The step control predictor} \]

The first 12 components of \( r^4 = r_3(1 : 13) \) are

\[ r_3(i) = c_i^4/i!, \quad i = 1, 2, \ldots, 12, \]

and the 13th component is

\[ r_3(13) = \frac{1}{b_{13}} \left[ \frac{1}{14!} - b_{12}S_2(13) - B_1(14) \right], \]

which corresponds to the Runge–Kutta order condition (11).

A truncated Taylor expansion of the right-hand side of (3) about \( x_n \) gives

\[ \sum_{j=0}^{15} S_3(j) h_n^j b_n^{(j)} \]

with coefficients

\[ S_3(j) = M^4(j, 1 : 13) u^3 = r_3(j) = \frac{c_j^4}{j!}, \quad j = 1, 2, \ldots, 12, \]

\[ S_3(j) = a_{32} S_2(j - 1) + \sum_{i=1}^{5} \gamma_i \frac{\eta_i^{j-1}}{(j-1)!} + \sum_{i=1}^{5} \gamma_i \frac{\eta_i^{j-2}}{(j-2)!} \quad j = 13, 14, 15. \]

4.4 The step control predictor \( P_4 \)

The 12-vector of the reordered coefficients of the step control predictor \( P_4 \) (5),

\[ u^4 = [a_{41}, \gamma_40, \beta_41, \gamma_41, \beta_42, \gamma_42, \beta_43, \gamma_43, \beta_44, a_{43}, \gamma_44]^T, \]

is the solution of the system of order conditions

\[ M^4 u^4 = r^4, \]

where

\[ M^4 = \]

\[ \begin{bmatrix}
1 & 0 & 1 & 0 & \cdots & 1 & 0 & 1 & 0 \\
0 & 1 & \eta_2 & 1 & \cdots & \eta_5 & 1 & c_3 & 1 \\
0 & 0 & \eta_2^{2/2!} & \eta_2 & \cdots & \eta_5^{2/2!} & \eta_5 & c_3^{2/2!} & \eta_6 \\
c & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & \eta_2^{11/11!} & \eta_2^{10/10!} & \cdots & \eta_5^{11/11!} & \eta_5^{10/10!} & c_3^{11/11!} & \eta_6^{10/10!}
\end{bmatrix} \]

(20)

and \( r^4 = r_4(1 : 12) \) has components

\[ r_4(i) = 1/i!, \quad i = 1, 2, \ldots, 12. \]

5 Symbolic elementary matrix functions

Consider the matrices

\[ M^\ell \in \mathbb{R}^{m_\ell \times m_\ell}, \quad \ell = 1, 2, 3, 4, \]

(21)

of the Vandermonde-type systems (13), (15), (17), and (19), where

\[ m_1 = 14, \quad m_2 = 12, \quad m_3 = 13, \quad m_4 = 12. \]

A fast solution of these systems in \( O(m_\ell^2) \) operations will be achieved by decomposing \( (M^\ell)^{-1} \) into the product of lower and upper bidiagonal matrices, one diagonal matrix and one upper tridiagonal matrix.

The purpose of this section is to construct elementary lower and upper bidiagonal symbolic matrix functions of the parameters of HBO14 to be used in Section 7 to diagonalize \( M_\ell, \ell = 1, 2, 3. \)

Since the Vandermonde-type matrices \( M^\ell \) can be decomposed into the product of a diagonal matrix containing reciprocals of factorials and a confluent Vandermonde matrix, the factorizations used in this paper hold following the approach of Björck and Pereyra [4], Krogh [16], Galimberti and Pereyra [8] and Björck and Elfving [3]. Pivoting is not needed in this decomposition because of the special structure of Vandermonde-type matrices.
5.1 Construction of lower bidiagonal matrices

We first describe the zeroing process of a general vector \( \mathbf{x} = [x_1, x_2, \ldots, x_m]^T \) with no zero elements. The lower bidiagonal matrix

\[
L_k = \begin{bmatrix}
I_{k-1} & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & 1 & -\tau_{k+1} & 0 & \cdots \\
\vdots & \vdots & \ddots & \ddots & \ddots \\
0 & 0 & 0 & 1 & -\tau_m \\
\end{bmatrix}
\]

\[(23)\]
defined by the multipliers

\[
\tau_i = \frac{x_{i-1}}{x_i} = -L_k(i, i), \quad i = k + 1, k + 2, \ldots, m,
\]

\[(24)\]
zeros the last \((m - k)\) components, \(x_{k+1}, \ldots, x_m\), of \(\mathbf{x}\).

For \(k = 3, 4, \ldots, m_\ell - 1\), left multiplying \(T = L_{k-1}^\ell \cdots L_4^\ell L_3^\ell M^\ell\) by \(L_k^\ell\) zeros the last \((m_\ell - k)\) components of the \(k\)th column of \(T\). Thus we obtain the upper triangular matrix

\[
L^\ell M^\ell = L_{m_\ell-1}^\ell \cdots L_4^\ell L_3^\ell M^\ell
\]

\[(25)\]
in \((m_\ell - 3)\) steps. We note that \(L^\ell\) does not change the first two rows of \(M^\ell\).

**Process 1.** At the \(k\)th step, starting with \(k = 3\),

- \(M^{\ell(k-1)} = L_{k-1}^\ell L_{k-2}^\ell \cdots L_3^\ell M^\ell\) is an upper triangular matrix in columns 1 to \(k - 1\).
- The multipliers in \(L_k^\ell\) are obtained from \(M^{\ell(k-1)}(k + 1 : m_\ell, k)\) since \(M^\ell(i, k) \neq 0\) for \(i = k + 1, k + 2, \ldots, m_\ell\).

Algorithm 1 in Appendix A describes this process.

5.2 Construction of initializing upper tridiagonal matrices \(U_1^\ell\) for \(M^\ell\)

The second step in diagonalizing \(M^\ell\) transforms the first two rows of \(L^\ell M^\ell\) by right multiplication by an upper tridiagonal matrix \(U_1^\ell\) such that

\[
L^\ell M^\ell U_1^\ell(1 : 2, 1 : m_\ell) = \begin{bmatrix}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 1 & \cdots & 1 \\
\end{bmatrix}
\]

\[(26)\]
The action of \(U_1^\ell\) amounts to take the divided difference of the odd-numbered columns of \(L^\ell M^\ell\) plus the last column if \(m_\ell\) is even (cf. [3]). The precise form of \(U_1^\ell\) is postponed until Section 7 since it is defined in terms of each \(M^\ell\).

5.3 Construction of upper bidiagonal matrices for \(M^\ell, \ell = 1, 2, 3\)

We construct upper bidiagonal matrices \(U_k^\ell\), \(k = 2, 3, \ldots, m_\ell - 1\) whose right multiplication on \(L^\ell M^\ell U_1^\ell\) amounts to take divided differences of order \(k\), for \(k = 2, 3, \ldots, m_\ell - 1\), of the columns \(k\) to \(m_\ell\) of the matrices on which they act.

Specifically, consider the two-row matrix:

\[
L^\ell M^\ell U_1^\ell \cdots U_{k-1}^\ell(k : k + 1, 1 : m_\ell)
\]

\[
= \begin{bmatrix}
y_{k1} & \cdots & y_{k,k-1} & 1 & 1 & \cdots & 1 & 1 \\
y_{k+1,1} & \cdots & y_{k+1,k-1} & y_{k+1,k} & y_{k+1,k+1} & \cdots & y_{k+1,m_\ell-1} & y_{k+1,m_\ell} \\
\end{bmatrix}
\]

\[(27)\]
and define the upper bidiagonal matrix

\[
U_k^\ell = \begin{bmatrix}
I_{k-1} & 0 & \cdots & 0 & \cdots & 0 & 0 \\
0 & 1 & -\sigma_{k+1} & 0 & \cdots & 0 & 0 \\
0 & 0 & \sigma_{k+1} & -\sigma_{k+2} & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & \sigma_{m_\ell-2} & -\sigma_{m_\ell-1} & 0 \\
0 & 0 & 0 & \cdots & 0 & \sigma_{m_\ell-1} & -\sigma_{m_\ell} \\
0 & 0 & 0 & \cdots & 0 & 0 & \sigma_{m_\ell}
\end{bmatrix}
\]

\[(28)\]
by means of the divisors

\[
\sigma_i = \frac{1}{y_{2,i} - y_{2,i-1}} = U_k^\ell(i, i), \quad i = k + 1, k + 2, \ldots, m_\ell.
\]

\[(29)\]
Then right multiplication of (27) by $U^\ell_k$ zeros the 1’s in positions $k + 1, \ldots, m_\ell$ in the first row of and puts 1’s in positions $k + 1, \ldots, m_\ell$ in the second row:

$$L^\ell M^\ell U^\ell_1 \cdots U^\ell_{k-1} U^\ell_k (k : k + 1, 1 : m_\ell) = \begin{bmatrix} y_{k1} & \cdots & y_{k,k-1} & 1 & 0 & \cdots & 0 & 0 \\ y_{k+1,1} & \cdots & y_{k+1,k-1} & y_{k+1,k} & 1 & \cdots & 1 & 1 \end{bmatrix}.$$ (30)

Applying $U^\ell_k$, $k = 2, 3, \ldots, m_\ell - 1$, on the right of the upper triangular matrix $L^\ell M^\ell U^\ell_k$, we obtain the diagonal matrix

$$D^\ell = L^\ell M^\ell U^\ell_e = L^\ell_{m_\ell-1} \cdots L^\ell_4 M^\ell U^\ell_2 \cdots U^\ell_1$$

in $(m_\ell - 2)$ steps.

**Process 2.** At the $k$th step, starting with $k = 2$,

- $M^{(k-1)} = (L^\ell M^\ell U^\ell_1) U^\ell_2 \cdots U^\ell_{k-1}$ is a diagonal matrix in rows 1 to $k - 1$.
- The divisors in $U^\ell_k$ are obtained from $M^{(k-1)}(k+1, k+1 : m_\ell)$ since $M^{(k-1)}(k+1, j) - M^{(k-1)}(k+1, j-1) \neq 0$ for $j = k+1, k+2, \ldots, m_\ell - 1$.

Algorithm 2 in Appendix A describes this process.

### 5.4 Construction of upper bidiagonal matrices for $M^4$

The construction of upper bidiagonal matrices for $M^4$ differs slightly from the construction for $M^\ell$, $\ell = 1, 2, 3$, and requires a consideration of its own. For the matrix $L^4 M^4 U^4_1$ we construct upper bidiagonal matrices $U^4_2, U^4_3, \ldots, U^4_{10}$ such that the upper triangular matrix $U^4 = U^4_1 U^4_2 \cdots U^4_{10}$ transforms $L^4 M^4$ into a matrix $W^4 = L^4 M^4 U^4$ with nonzero diagonal elements, $W^4(i, i) \neq 0$, $i = 1, 2, \ldots, 12$, and nonzero second to last elements, $W^4(2 : 12, 12) \neq 0$, in the last column, and zero elsewhere. We call such a matrix a “diagonal+last-column” matrix.

We describe the zeroing process of the upper bidiagonal matrix $U^4_k$ on the two-row matrix

$$L^4 M^4 U^4_1 \cdots U^4_{k-1} (k : k + 1, 1 : 12)$$

which differs from matrix (27) in the last column. The divisors

$$\sigma_i = \frac{1}{y_{2,i} - y_{2,i-1}} = U^4_k(i, i), \quad i = k + 1, k + 2, \ldots, 11,$$ (33)

define

$$U^4_k = \begin{bmatrix} I_{k-1} & 0 & \cdots & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & \sigma_{k+1} & \cdots & 0 & 0 \\ 0 & 0 & \cdots & \sigma_{k+1} & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & \sigma_{10} & \cdots & 0 & 0 \\ 0 & 0 & \cdots & 0 & \cdots & \sigma_{11} & 0 \\ 0 & 0 & \cdots & 0 & \cdots & 0 & 1 \end{bmatrix}$$ (34)

which differs from matrix (28) in the last column. Right-multiplication of (32) by $U^4_k$ zeros the 1’s in position $k, \ldots, 11$ in the first row and puts 1’s in position $k + 1, \ldots, 11$ in the second row:

$$L^4 M^4 U^4_1 \cdots U^4_{k-1} U^4_k (k : k + 1, 1 : 12) = \begin{bmatrix} y_{k1} & \cdots & y_{k,k-1} & 1 & 0 & \cdots & 0 & y_{k,12} \\ y_{k+1,1} & \cdots & y_{k+1,k-1} & y_{k+1,k} & 1 & \cdots & 1 & y_{k+1,12} \end{bmatrix}.$$ (35)

Thus, $U^4 = U^4_1 U^4_2 \cdots U^4_{10}$ transforms the upper triangular matrix $L^4 M^4$ of (25) into the diagonal+last-column matrix

$$W^4 = L^4 M^4 U^4_1 U^4_2 \cdots U^4_{10}$$

in ten steps.
Process 3. At the $k$th step, starting with $k = 2$,
- $M^{4(k-1)} = L^4 M^4 U^4_k U^2_{k-1} \ldots U^4_1$ is a diagonal+last column matrix in rows 1 to $k - 1$.
- The divisors in $U^k_k$ are obtained from $M^{4(k-1)}(k+1,k+1:12)$ since $M^{4(k-1)}(k+1,j) - M^{4(k-1)}(k+1,j-1) \neq 0$, $j = k + 1, k + 2, \ldots, 11$.

Algorithm 3 in Appendix A describes this process.

6 Particular variable step HBO14

In the general HBO14 of section 2, $c_2$ and $c_3$ are free parameters. After an appropriate choice of $c_2$ and $c_3$, one has a particular variable step HBO14 that depends only on $h_{n+1}$ and the previous nodes, $x_n, x_{n-1}, \ldots, x_{n-5}$, which determine $\eta_2, \ldots, \eta_6$ in (9).

After extensive numerical experimentation, a good particular variable step HBO14 was obtained with

$$c_1 = 0, \quad c_2 = \frac{2}{3}, \quad c_3 = 1.$$  (37)

The remaining of this paper is concerned with the particular variable step HBO14 with coefficients $c_j$ given in (37).

The procedure to advance integration from $x_n$ to $x_{n+1}$ is as follows.

(a) The steps, $h_{n+1}$, is obtained by formula (55) of section 9.
(b) The numbers $\eta_2, \ldots, \eta_6$, defined in (9), are calculated.
(c) The coefficients of integration formula IF, predictors $P_2, P_3$ and step control predictor $P_4$ are obtained successively as solutions of systems (13), (15), (17) and (19), respectively.
(d) The values $y_{n+c_2}, y_{n+c_3}, y_{n+1}$, and $\accentset{\cdot}{y}_{n+1}$ are obtained by formulae (2)–(5).
(e) The step is accepted if $|y_{n+1} - \accentset{\cdot}{y}_{n+1}|$ is smaller than the chosen tolerance and the program goes to (a) with $n$ replaced by $n + 1$. Otherwise the program returns to (a) and a new smaller stepsze $h_{n+1}$ is computed.

7 Fast solution of particular HBO14

The elementary matrices $L^\ell_k$ and $U^\ell_k$, $\ell = 1, 2, 3, 4$, are constructed only once as functions of $\eta_2, \ldots, \eta_6$. Then these functions are used by the fast Algorithms 4 and 5 in Appendix A to solve systems (13), (15), (17), and (19) at each integration step.

7.1 Solution of $M^1 u^1 = r^1$

Firstly, the elimination procedure of subsection 5.1 is applied to $M^1$ of (14) to construct $14 \times 14$ lower bidiagonal matrices $L^1_k$, $k = 3, \ldots, 13$, of the form (23) defined by the multipliers

$$\tau_i = \frac{i + 2 - k}{\mu^1(k)} = -L^1_k(i,i), \quad i = k + 1, k + 2, \ldots, 14,$$  (38)

where

$$\mu^1(k) = \begin{cases} M^1(2,k), & k = 1, 3, 5, \ldots, 13, \\ M^1(3,k), & k = 2, 4, 6, \ldots, 12. \end{cases}$$

Left multiplying $M^1$ by $L^1_k$, $k = 3, \ldots, 13$, produces the upper triangular matrix $L^1 M^1 = L^1_{13} \cdots L^1_3 M^1$ of the form (25), where $m_4 = 14$.

Secondly, we construct the upper tridiagonal matrix $U^1_1$ which transforms the matrix $M^1$ into the matrix of first order divided differences $M^1 U^1_1$ of the odd-numbered columns of $M^1$ plus the last one where the divisors are taken from the second row of $M^1$. The diagonal entries of $U^1_1$ are ones, except for

$$U^1_1(1,1) = \frac{1}{\eta_2}, \quad U^1_1(5,5) = \frac{1}{\eta_3 - \eta_2}, \quad U^1_1(7,7) = \frac{1}{\eta_4 - \eta_3}, \quad U^1_1(9,9) = \frac{1}{\eta_5 - \eta_4},$$

$$U^1_1(11,11) = \frac{1}{\eta_6 - \eta_5}, \quad U^1_1(13,13) = \frac{1}{c_3 - \eta_6}, \quad U^1_1(14,14) = \frac{1}{c_2 - c_3}.$$
and the non-diagonal entries are zeros, except for
\[ U_1^2(i - 2, i) = -U_1^1(i, i), \quad i = 3, 5, 7, \ldots, 13, \]
\[ U_1^1(13, 14) = -U_1^1(14, 14). \]

The first two rows of \( M^1 U_1^1 \) are as in (26).

Thirdly, the elimination procedure of subsection 5.3 is used to construct \( 14 \times 14 \) upper bidiagonal matrices \( U_k^1, k = 2, \ldots, 13 \), of the form (28) defined by the divisors
\[ \sigma_i = \frac{k}{\mu_1(i) - \mu_1(i - k)} = U_k^1(i, i), \quad i = k + 1, k + 2, \ldots, 14. \]

Right multiplying \( L^1 M^1 \) by \( U_k^1, k = 1, \ldots, 13 \), produces the diagonal matrix
\[ D^1 = L_{13}^1 L_{12}^1 \cdots L_3^1 M^1 U_2^1 \cdots U_{13}^1, \]
where
\[ D^1(i, i) = 1, \quad i = 1, 2, 3, \]
and
\[ D^1(i, i) = \frac{(i - 1)!}{2[\mu_1(3)][\mu_1(4)] \cdots [\mu_1(i - 1)]}, \quad i = 4, 5, \ldots, 14. \]

Lastly, \( M^1 \) is decomposed into the product of elementary matrices:
\[ M^1 = (L_{13}^1 L_{12}^1 \cdots L_3^1)^{-1} D^1 (U_1^1 U_2^1 \cdots U_{13}^1)^{-1} \]
and the solution of system (13) is
\[ u^1 = U_1^1 U_2^1 \cdots U_{13}^1 (D^1)^{-1} L_{13}^1 L_{12}^1 \cdots L_3^1 r^1, \]
where fast computation goes from right to left.

**Process 4.** Procedure (40) is implemented in the following steps:

- Algorithm 4 overwrites \( r^1 = r_1(1 : m) \) with \( U_1^1 r^1 \),
  \[ r_1(i) = r_1(i) U_1^1(i, i), \quad i = 3, 5, 7, \ldots, m - 1, \]
  \[ r_1(i) = r_1(i) - r_1(i + 2), \quad i = 1, 3, 5, \ldots, m - 3, \]
  \[ r_1(14) = r_1(14) U_1^1(14, 14), \]
  \[ r_1(13) = r_1(13) - r_1(14). \]

### 7.2 Solution of \( M^2 u^2 = r^2 \)

Firstly, the elimination procedure of subsection 5.1 is applied to \( M^2 \) of (16) to construct \( 12 \times 12 \) lower bidiagonal matrices \( L_k^2, k = 3, \ldots, 11 \), of the form (23) defined by the multipliers
\[ \tau_i = \frac{i + 2 - k}{\mu_2(k)} = -L_k^2(i, i), \quad i = k + 1, k + 2, \ldots, 12, \]
where
\[ \mu_2(k) = \begin{cases} 
M_2^2(2, k), & k = 1, 3, 5, \ldots, 11, \\
M_2^2(3, k), & k = 2, 4, 6, \ldots, 10.
\end{cases} \]

Left multiplying \( M^2 \) by \( L_k^2, k = 3, \ldots, 11 \), produces the upper triangular matrix \( L^2 M^2 = L_{11}^2 \cdots L_3^2 M^2 \) of the form (25), where \( m_2 = 12 \).

Secondly, we construct the upper tridiagonal matrix \( U_2^2 \) which transforms the matrix \( M^2 \) into the matrix of first order divided differences \( M^2 U_2^2 \) of the odd-numbered columns of \( M^2 \) where the divisors are taken from the second row of \( M^2 \).
The diagonal entries of \( U_1^2 \) are ones, except for
\[
U_1^2(3, 3) = \frac{1}{\eta_2}, \quad U_1^2(5, 5) = \frac{1}{\eta_3 - \eta_2}, \quad U_1^2(7, 7) = \frac{1}{\eta_4 - \eta_3},
\]
and the non-diagonal entries are zeros, except for
\[
U_1^2(i - 2, i) = -U_1^2(i, i), \quad i = 3, 5, 7, \ldots, 11.
\]
The first two rows of \( M^2 U_1^2 \) are as in equation (26).

Thirdly, the elimination procedure of subsection 5.3 is used to construct \( 12 \times 12 \) upper bidiagonal matrices \( U_k^2 \), \( k = 2, \ldots, 12 \), of the form (28) defined by the divisors
\[
\sigma_i = \frac{k}{\mu_2(i) - \mu_2(i - k)} = U_k^2(i, i), \quad i = k + 1, k + 2, \ldots, 12. \tag{42}
\]
Right multiplying \( L^2 M^2 \) by \( U_k^2 \), \( k = 1, \ldots, 11 \), produces the diagonal matrix
\[
D^2 = L_{10}^2 \cdots L_3^2 M^2 U_2^2 \cdots U_{11}^2,
\]
where
\[
D^2(i, i) = 1, \quad i = 1, 2, 3,
\]
and
\[
D^2(i, i) = \frac{(i - 1)!}{2^{|\mu_2(3)|} \cdots |\mu_2(i - 1)|}, \quad i = 4, 5, \ldots, 12.
\]
Finally, \( M^2 \) is decomposed into the product of elementary matrices:
\[
M^2 = (L_{11}^2 L_{10}^2 \cdots L_3^2)^{-1} D^2 (U_2^2 U_3^2 \cdots U_{11}^2)^{-1},
\]
and the solution of system (15) is
\[
u^2 = U_2^1 U_3^2 \cdots U_{11}^2 (D^2)^{-1} L_{11}^2 L_{10}^2 \cdots L_3^2 r^2,
\tag{43}
\]
where fast computation goes from right to left.

Process 5. Procedure (43) is implemented in the following steps:

- Algorithm 4 overwrites \( r^2 = r_2(1 : m) \) with \( U_1^2 r^2 \) in \( O(m^2) \) operations, where \( m = 12 \). The input is \( M = M^2 \); \( m = 12 \); \( r = r^2 \); \( L_k = L_k^2 \), \( k = 3, 4, \ldots, m - 1 \); \( U_k = U_k^2 \), \( k = 2, \ldots, m - 1 \); and \( D = D^2 \).

- The following iteration overwrites \( r^2 = r_2(1 : m) \) with \( U_1^2 r^2 \):
\[
\begin{align*}
r_2(i) &= r_2(i) U_1^2(i, i), \quad i = 3, 5, 7, \ldots, m - 1, \\
r_2(i) &= r_2(i) - r_2(i + 2), \quad i = 1, 3, 5, \ldots, m - 3.
\end{align*}
\]

7.3 Solution of \( M^3 u^3 = r^3 \)

Firstly, the elimination procedure of subsection 5.1 is applied to \( M^3 \) of (18) to construct \( 13 \times 13 \) lower bidiagonal matrices \( L_k^3 \), \( k = 3, \ldots, 12 \), of the form (23) defined by the multipliers
\[
\tau_i = \frac{i + 2 - k}{\mu_3(k)} = -L_3^3(i, i), \quad i = k + 1, k + 2, \ldots, 13, \tag{44}
\]
where
\[
\mu_3(k) = \begin{cases} 
M^3(2, k), & k = 1, 3, 5, \ldots, 13, \\
M^3(3, k), & k = 2, 4, 6, \ldots, 12.
\end{cases}
\tag{45}
\]
Left multiplying \( M^3 \) by \( L_k^3 \), \( k = 3, \ldots, 13 \), produces the upper triangular matrix \( L_3^3 M^3 = L_{12}^3 \cdots L_3^3 M^3 \) of the form (25), where \( m_3 = 13 \).

Secondly, we construct the upper tridiagonal matrix \( U_1^3 \) which transforms the matrix \( M^3 \) into the matrix of first order divided differences \( M^3 U_1^3 \) of the odd-numbered columns of \( M^3 \) where the divisors are taken from the second row of \( M^3 \).
The diagonal entries of $U_1^3$ are ones, except for

$$U_1^3(3, 3) = \frac{1}{\eta_2}, \quad U_1^3(5, 5) = \frac{1}{\eta_3 - \eta_2}, \quad U_1^3(7, 7) = \frac{1}{\eta_4 - \eta_3},$$

and the non-diagonal entries are zeros, except for

$$U_1^3(i - 2, i) = -U_1^3(i, i), \quad i = 3, 5, 7, \ldots, 13.$$

The first two rows of $M^3 U_1^3$ are as in equation (26).

Thirdly, the elimination procedure of subsection 5.3 is used to construct $13 \times 13$ upper bidiagonal matrices $U^3_k$, $k = 2, \ldots, 12$, of the form (28) defined by the divisors

$$\sigma_i = \frac{k}{\mu_3(i) - \mu_3(i - k)} = U^3_k(i, i), \quad i = k + 1, k + 2, \ldots, 13. \quad (46)$$

Right multiplying $L^3 M^3$ by $U^3_k$, $k = 1, \ldots, 12$, produces the diagonal matrix

$$D^3 = L^3_{12} L^3_{11} \cdots L^3_3 M^3 U^3_2 U^3_3 \cdots U^3_{12},$$

where

$$D^3(i, i) = 1, \quad i = 1, 2, 3,$$

and

$$D^3(i, i) = \frac{(i - 1)!}{2 \prod \{-\mu_3(3)\} \cdots \{-\mu_3(i - 1)\}}, \quad i = 4, 5, \ldots, 13.$$

Lastly, we have the following factorization of $M^3$ into elementary matrices:

$$M^3 = (L^3_{12} L^3_{11} \cdots L^3_5)^{-1} D^3 (U^3_1 U^3_2 \cdots U^3_{12})^{-1},$$

and the solution of system (17) is

$$u^3 = U^3_1 U^3_2 \cdots U^3_{12} (D^3)^{-1} L^3_{12} L^3_{11} \cdots L^3_3 r^3, \quad (47)$$

where fast computation goes from right to left.

**Process 6.** Procedure (47) is implemented in the following steps:

- Algorithm 4 overwrites $r^3 = r_3(1 : m)$ with $U^3_1 r^3$:
  $$r_3(i) = r_3(i) U^3_1(i, i), \quad i = 3, 5, 7, \ldots, m,$$
  $$r_3(i) = r_3(i) - r_3(i + 2), \quad i = 1, 3, 5, \ldots, m - 2.$$

**7.4 Solution of $M^4 u^4 = r^4$**

The solution procedure for the step control predictor $P_4$ differs slightly from the the procedure for IF, $P_2$ and $P_3$, and requires a treatment of its own.

Firstly, the elimination procedure of subsection 5.1 is applied to $M^4$ of (20) to construct $12 \times 12$ lower bidiagonal matrices $L^4_k$, $k = 3, \ldots, 11$,

$$L^4_k = \begin{bmatrix}
I_{k-1} & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & 1 & -\tau_{k+1} & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 1 & -\tau_{12}
\end{bmatrix}, \quad (48)$$

defined by the multipliers

$$\tau_i = \frac{i + 2 - k}{\mu_4(k)} = -L^4_k(i, i), \quad i = k + 1, k + 2, \ldots, 12. \quad (49)$$
where

\[ \mu_4(k) = \begin{cases} 
   M^4(2, k), & k = 1, 3, 5, \ldots, 11, \\
   M^4(3, k), & k = 2, 4, 6, \ldots, 10.
\end{cases} \]  

(50)

Left multiplying \( M^4 \) by \( L_k^4 \), \( k = 3, \ldots, 11 \), produces the upper triangular matrix \( L_k^4 M^4 = L_{11}^4 \cdots L_4^4 M^4 \) of the form (25), where \( m_4 = 12 \).

Secondly, we construct the upper tridiagonal matrix \( U_1^4 \) which transforms the matrix \( M^4 \) into the matrix of first order divided differences \( M^4 U_1^4 \) of the odd-numbered columns of \( M^4 \) where the divisors are taken from the second row of \( M^4 \).

The diagonal entries of \( U_1^4 \) are ones, except for

\[ U_1^4(3, 3) = \frac{1}{\eta_2}, \quad U_1^4(5, 5) = \frac{1}{\eta_3 - \eta_2}, \quad U_1^4(7, 7) = \frac{1}{\eta_4 - \eta_3}, \]

\[ U_1^4(9, 9) = \frac{1}{\eta_5}, \quad U_1^4(11, 11) = \frac{1}{\eta_5 - \eta_4}, \]

and the non-diagonal entries are zeros, except for

\[ U_1^4(i - 2, i) = -U_1^4(i, i), \quad i = 3, 5, 7, \ldots, 11. \]

The first two rows of \( M^4 U_1^4 \) are as in equation (26).

Thirdly, the elimination procedure of subsection 5.4 is used to construct \( 12 \times 12 \) upper bidiagonal matrices \( U_k^4 \), \( k = 2, \ldots, 10 \), defined by the divisors

\[ \sigma_i = \frac{k}{\mu_4(i) - \mu_4(i - k)} = U_k^4(i, i), \quad i = k + 1, k + 2, \ldots, 11, \]

(51)

Right multiplying \( L_k^4 M^4 \) by \( U_k^4 \), \( k = 1, \ldots, 10 \), produces a diagonal+last-column matrix \( W^4 \) of the form (36).

Next, a factored Gaussian elimination by means of \( L_{13}^4 L_{12}^4 \) diagonalizes \( W^4 \) as follows. First, \( W^4(12, 12) \) is set to 1 by the diagonal matrix \( L_{12}^4 \):

\[ L_{12}^4(i, i) = 1, \quad i = 1, \ldots, 11, \]

\[ L_{12}^4(12, 12) = 1/W^4(12, 12). \]

Then, the non-diagonal entries in the last column of \( L_{12}^4 W^4 \) are zeroed by the unit diagonal+last-column matrix \( L_{13}^4 \) whose last column has top 11 entries

\[ L_{13}^4(1 : 11, 12) = -(L_{12}^4 W^4)(1 : 11, 12). \]

This procedure transforms \( M^4 \) into the diagonal matrix

\[ D^4 = L_{13}^4 L_{12}^4 \cdots L_3^4 M^4 U_1^4 U_2^4 \cdots U_{10}^4, \]

where

\[ D^4(i, i) = 1, \quad i = 1, 2, 3, 12, \]

and

\[ D^4(i, i) = \frac{(i - 1)!}{2[-\mu_4(3)] [-\mu_4(4)] \cdots [-\mu_4(i - 1)]}, \quad i = 4, 5, \ldots, 11. \]

Lastly, \( M^4 \) is decomposed into the product of elementary matrices,

\[ M^4 = (L_{13}^4 L_{12}^4 \cdots L_3^4)^{-1} D^4 (U_1^4 U_2^4 \cdots U_{10}^4)^{-1}, \]

and the solution of system (19) is

\[ u^4 = U_1^4 U_2^4 \cdots U_{10}^4 (D^4)^{-1} L_{13}^4 L_{12}^4 \cdots L_4^4 r^4, \]

(52)

where fast computation goes from right to left.

Procedure (52) is implemented in Algorithm 5 in Appendix A in \( O(m^2) \) operations, where \( m = 12 \). The input is \( M = M^4; m = 12; r = r^4; L_k = L_k^4, k = 3, 4, \ldots, 13; U_k = U_k^4, k = 1, 2, \ldots, 10; \) and \( D = D^4 \). The output is \( u = u^4 \).
Remark 1. Formulae (2)–(5) can be put in matrix form. For instance, (4) can be written as
\[
y_{n+1} = y_n + F^{1} u^{1},
\]
where
\[
F^{1} = h_{n+1} \left[ f_n, h_{n+1} f_{n}', f_{n-1}, h_{n+1} f_{n-1}', f_{n-2}, h_{n+1} f_{n-2}', f_{n-3}, h_{n+1} f_{n-3}',
\right.
\]
\[
\left. f_{n-4}, h_{n+1} f_{n-4}', f_{n-5}, h_{n+1} f_{n-5}', f_{n+c_2}, f_{n+c_3} \right],
\]
and
\[
u^{1} = \left[ b_{11}, \gamma_{10}, \beta_{11}, \gamma_{11}, \beta_{12}, \gamma_{12}, \beta_{13}, \gamma_{13}, \beta_{14}, \gamma_{14}, \beta_{15}, \gamma_{15}, b_{12} \right]^T.
\]
It is interesting to note the three decomposition forms of the system \( Fu \):
\[
F(UD^{-1} Lr) \quad \text{(generalized Lagrange interpolation),}
\]
\[
(FUD^{-1}) Lr \quad \text{(Krogh’s modified divided differences),}
\]
\[
(FUD^{-1} L)r \quad \text{(Nordsieck’s formulation).}
\]
The first form is used in this paper, the second form for Vandermonde systems is found in [16], and the third form is found in [20].

8 Region of absolute stability and principal error term

To obtain the region of absolute stability, \( R \), of HBO14 we apply the predictors \( P_2, P_3 \) and the integration formula \( IF \), with constant \( h \), to the linear test equation
\[
y' = \lambda y, \quad y_0 = 1.
\]
This gives the difference equation and the corresponding characteristic equation
\[
\sum_{j=0}^{6} \gamma_j y_{n+j} = 0, \quad \sum_{j=0}^{6} \gamma_j r^j = 0,
\]
respectively. A complex number \( \lambda h \) is in \( R \) if the six roots of the characteristic equation satisfy the root condition \( |r_s| \leq 1 \) and the multiple roots satisfy \( |r_s| < 1 \). The method used to find \( R \) is similar to the one used for \( k \)-step multistep methods (see [12, pp. 256–257]). The gray region in Fig. 1 is the upper-half of region \( R \), which is symmetric with respect to the real axis. The interval of absolute stability is \( (\alpha, 0) = (-0.39, 0) \). It is seen that HBO14 has a larger interval of absolute stability than the Adams–Bashforth–Moulton methods of orders 10 to 13 in PECE mode [22, pp. 139–140].

The principal error term of HBO14 is
\[
\left[ \delta_1 \{ f^{14} \} + 14 \delta_2 \{ \{ f^{12} \} f \} + \delta_3 \{ 2 f^{13} \}^2 + \delta_4 \{ 3 f^{12} \}^3 \right] h^{15},
\]
where \( \{ f^{14} \}, \{ \{ f^{12} \} f \}, \{ 2 f^{13} \}^2, \{ 3 f^{12} \}^3 \) are elementary differentials defined in [5], [17] and [11]. The principal local truncation coefficients of the principal error term are
\[
[\delta_1, 14 \delta_2, \delta_3, \delta_4] = \left[ -\frac{1}{1200606847}, -\frac{14}{3212565}, \frac{1}{8337285}, \frac{1}{229499} \right]
\]
with \( \ell_2 \)-norm 6.16e-06, which is quite small.
9 Controlling stepsize

The estimate $y_n - \tilde{y}_n$ and the current step $h_n$ are used to calculate the next stepsize $h_{n+1}$ by means of formula [13]

$$h_{n+1} = \min \left\{ h_{\text{max}}, \beta h_n \left[ \frac{\text{tolerance}}{|y_n - \tilde{y}_n|} \right]^{1/\kappa}, 4h_n \right\},$$  \hspace{1cm} (55)

with $\kappa = 13$ and safety factor $\beta = 0.81$.

10 Numerical results

The numerical performance of HBO14 and MATLAB’s ode113 is compared on the following problems: Arenstorf’s orbits [1], the Brusselator and the Pleiades [11, pp. 244–249], Euler’s equation and the restricted three-body problem [22, pp. 232–259], and the following nonstiff DETEST problems: growth problem of two conflicting populations B1, two-body problems D1–D5, and Van der Pol’s equation E2 with $\epsilon = 1$ [13].

The six starting values for HBO14 were obtained by DP(5,4)7Fm (see [7]) with initial step size, $h_1$, chosen by a method similar to steps (a) and (b) of [11, p. 169].

Computations were performed on a Mac with a dual 2.5 GHz PowerPC G5 and 4 GB DDR SSRAM running under Mac OS X Version 10.4.2 and MATLAB Version 7.0.4.352 (R14) Service Pack 2. Algorithms 4 and 5 were written in C and made into system-dependent MATLAB mex files for speed.

10.1 CPU against maximum global error

The maximum global error, MGE, was obtained from the errors corresponding to each integration step. These errors were calculated from the numerical value $y_{n+1}$ of HBO14 and the “exact solution” obtained by MATLAB’s ode113 with stringent tolerance $5 \times 10^{-14}$.

The cpu time was obtained from the curves which fit, in a least-square sense, the data $(\log_{10}(|MGE|), \log_{10}(CPU))$ using, say, MATLAB’s polyfit.

In Figs. 2 and 3, CPU (horizontal axis) is plotted versus $\log_{10}(|MGE|)$ (vertical axis) for the problems considered in this paper.

10.2 CPU percentage efficiency gain of HBO14 against ode113

The cpu percentage efficiency gain (CPU PEG) is defined by formula (cf. Sharp [24]),

$$(CPU\ PEG)_i = 100 \left( \frac{\sum_j CPU_{2,ij}}{\sum_j CPU_{1,ij}} - 1 \right),$$

where CPU$_{1,ij}$ and CPU$_{2,ij}$ are the CPU of methods 1 and 2, respectively, associated with problem $i$, and $j = -\log_{10}(|MGE|)$.

The CPU PEG for the problems considered in this paper is listed in Table 1.

It is seen from Figs. 2 and 3 and Table 1 that HBO14 compares favorably with MATLAB’s ode113 on the basis of CPU versus MGE.

10.3 Maximum global error against tolerance

Table 2 lists several numerical results related to the step control for the problems in hand on the time interval $[0, t_f]$ with set tolerance (TOL), namely, cpu time (CPU), number of function evaluations (NFE), number of failed attempts (REJ) and maximum global error (MGE) of HBO14 and ode113. For HBO14, NFE splits into 75% and 25% between $f$ and $f'$, respectively.

It is seen from Table 2 that HBO14 has smaller maximum global error than ode113 for each given tolerance.

11 Conclusion

A fast variable step 3-stage Hermite–Birkhoff–Obrechkoff method of order 14 with 5 backsteps was constructed by solving Vandermonde-type systems satisfying multistep and Runge–Kutta type order conditions. The stepsize is controlled by a local error estimator. This method, in its vectorized Lagrange form, was tested on the Brusselator, Euler’s equation, Arenstorf’s orbits, the restricted three-body problem, the Pleiades, and the following nonstiff DETEST problems: two-body problems of class D, the growth problem of two conflicting populations of class B and Van der Pol’s equation of class E. It is seen from subsections 10.1 and 10.2 that the new method has lower global error, uses less cpu time and requires fewer function evaluations than the highly optimized MATLAB’s ode113 for the problems in hand.

Acknowledgment

The anonymous referee is deeply thanked for many constructive comments and corrections. Thanks are also due to Philip W. Sharp for helpful discussions and observations.
Table 2: For each problem, time interval $[0, t_f]$ and tolerance (TOL), the table lists cpu time (CPU), number of function evaluations (NFE), number of failed attempts (REJ) and maximum global error (MGE) in corresponding left and right columns for HBO14 and ode113, respectively.

A Algorithms

Algorithm 1. This algorithm constructs lower bidiagonal matrices $L_k$ as functions of $c_2$, $c_3$ and $\eta_j$, $j = 2 : 6$.

For $k = 3 : m - 1$, do the following iteration:

For $i = m : -1 : k + 1$, do the following two steps:

Step (1) $L_k(i, i) = -A(i - 1, k)/A(i, k)$.

Step (2) For $j = k : m$, compute:

$$A(i, j) = A(i - 1, j) + A(i, j)L_k(i, i).$$

Algorithm 2. This algorithm constructs upper bidiagonal matrices $U_k$ (applied to $F_1, P_2, P_3$) as functions of $c_2$, $c_3$ and $\eta_j$, $j = 2 : 6$.

For $k = 2 : m - 1$, do the following iteration:

For $j = m : -1 : k + 1$, do the following two steps:

Step (1) $U_k(j, j) = 1/[A(k + 1, j) - A(k + 1, j - 1)]$.

Step (2) For $i = k : j$, compute

$$A(i, j) = (A(i, j) - A(i, j - 1))U_k(j, j).$$

Algorithm 3. This algorithm constructs upper bidiagonal matrices $U_k$ (applied to $P_4$) as functions of $c_2$, $c_3$ and $\eta_j$, $j = 2 : 6$.

For $k = 2 : m - 2$, do the following iteration:

For $j = m - 1 : -1 : k + 1$, do the following two steps:

Step (1) $U_k(j, j) = 1/[A(k + 1, j) - A(k + 1, j - 1)]$.

Step (2) For $i = k : j$, compute

$$A(i, j) = (A(i, j) - A(i, j - 1))U_k(j, j).$$
Algorithm 4. This algorithm overwrites \( r = r(1:m) \) with \( U_2 \cdots U_{m-1}(D^1)^{-1}L_{m-1}L_{m-2} \cdots L_3 r \) in \( O(m^2) \) operations for \( P_2 \) and \( P_3 \).

Given \([\eta_2, \eta_3, \ldots, \eta_k]\) and \( r = r(1:m) \), the following algorithm overwrites \( r \) with \( U_2 \cdots U_{m-1}(D^1)^{-1}L_{m-1}L_{m-2} \cdots L_3 r \).

Step (1) The following iteration overwrites \( r = r(1:m) \) with \( L_{m-1}L_{m-2} \cdots L_3 r \):

for \( k = 3:m-1 \), compute

\[
r(i) = r(i-1) + r(i)L_k(i,i), \quad i = m:-1:k+1.
\]

Step (2) The following iteration overwrites \( r = r(1:m) \) with \( U_2U_3 \cdots U_{m-1}D^{-1}r \):

\[
r(i) = r(i)/D(i,i), \quad i = 1:m.
\]

For \( k = m-1:-1:2 \), compute

\[
r(i) = r(i)U_k(i,i), \quad i = k+1:m,
\]

\[
r(i) = r(i) - r(i+1), \quad i = k:m-1.
\]

Algorithm 5. This algorithm solves the \( P_4 \) system \( P_4 \) in \( O(m^2) \) operations.

Given \([\eta_2, \eta_3, \ldots, \eta_k]\) and \( r = r(1:m) \), the following algorithm overwrites \( r \) with the solution \( u = u(1:m) \) of the system \( M u = r \).

Step (1) The following iteration overwrites \( r = r(1:m) \) with \( L_{m-1}L_{m-2} \cdots L_3 r \):

for \( k = 3:m-1 \), compute

\[
r(i) = r(i-1) + r(i)L_k(i,i), \quad i = m:-1:k+1.
\]

Step (2) First put

\[
G(1:m) = M(1:m,m).
\]

We obtain the coefficients of the last two row transformations, \( L_m \) and \( L_{m+1} \), by means of the recursion:

for \( k = 3:m-1 \), compute

\[
G(i) = G(i-1) + G(i)L_k(i,i), \quad i = m:-1:k+1.
\]

Step (3) The following computation overwrites the newly obtained \( r \) with \( L_{m+1}L_mr \):

\[
r(m) = r(m)/G(m),
\]

and for \( k = m-1:-1:1 \), compute

\[
r(k) = r(k) - G(k)r(m).
\]

Step (4) The following iteration overwrites \( r = r(1:m) \) with \( U_2U_3 \cdots U_{m-2}D^{-1}r \):

\[
r(i) = r(i)/D(i,i), \quad i = 1:m.
\]

For \( k = m-2:-1:2 \), compute

\[
r(i) = r(i)U_k(i,i), \quad i = k+1:m-1,
\]

\[
r(i) = r(i) - r(i+1), \quad i = k:m-2.
\]

Step (5) The following iteration overwrites \( r = r(1:m) \) with \( U_1r \):

\[
r(i) = r(i)U_1(i,i), \quad i = 3:2:m-1,
\]

\[
r(i) = r(i) - r(i+2), \quad i = 1:2:m-3.
\]

Algorithms 4 and 5 use minimum storage since the solution is obtained by successively transforming the right-hand side into the solution vector. This is an advantage compared to generating \( m \times m \) triangular matrices as an intermediate result at each integration step.
B Matlab programming

Algorithm 4 which solves systems IF, P_2 and P_3 was programmed in C and compiled by the MATLAB mex command into mex files, say, IF.macamex, P2.macamex and P3.macamex.

Algorithm 5 which solves the P_4 system was programmed in C and compiled by the MATLAB mex command into a mex file, say, SCP.macamex.

At runtime, the data of differential equations were input. Then, IF.macamex, P2.macamex, P3.macamex and SCP.macamex were called and run to calculate the values of the coefficients of IF, P_2, P_3 and P_4 at each integration step until completion of the integration. CPU time and number of evaluations of f(x,y) and f'(x,y) for the runtime of Algorithms 4 and 5 were recorded.

The option MGE can be run.

MATLAB’s ode113 can be run with appropriate tolerance for comparison with HBO14.

The elementary matrix functions L_ℓ^j and U_ℓ^j, ℓ = 1, 2, 3, 4, are constructed by Algorithms 1 and 2 as functions of η_j, for j = 2, 3, . . . , 6. These algorithms are not needed at runtime since these matrix functions are already implemented in the MATLAB mex files IF.macamex, P2.macamex, P3.macamex and SCP.macamex.
